FUSION PROTEINS, THEIR PREPARATION AND USE

This is a continuation-in-part of co-pending U.S. Patent Application Serial No. 07/399,874 filed August 29, 1989.

5 FIELD OF THE INVENTION

The present invention relates to fusion proteins and a process for preparing fusion proteins. The invention also pertains to various oligonucleotide and amino acid sequences which make up fusion proteins of
10 the present invention.

BACKGROUND OF THE INVENTION

Proteins, which in addition to the desired protein, also have an undesirable constituent or "ballast" constituent in the end product are referred
15 to as fusion proteins. When proteins are prepared by genetic engineering, the intermediate stage of a fusion protein is utilized particularly if, in direct expression, the desired protein is decomposed relatively rapidly by host-endogenous proteases,
20 causing reduced or entirely inadequate yields of the desired protein.

The magnitude of the ballast constituent of the fusion protein is usually selected in such a manner that an insoluble fusion protein is obtained. This
25 insolubility not only provides the desired protection against the host-endogenous proteases but also permits easy separation from the soluble cell components. It is usually accepted that the proportion of the desired protein in the fusion protein is relatively small,

-2-

i.e. that the cell produces a relatively large quantity of "ballast".

The preparation of fusion proteins with a short ballast constituent has been attempted. For example, a gene fusion was prepared which codes for a fusion protein from the first ten amino acids of β -galactosidase and somatostatin. However, it was observed that this short amino acid chain did not adequately protect the fusion protein against decomposition by the host-endogenous proteases (US-A 4 366 246, Column 15, Paragraph 2).

From EP-A 0 290 005 and 0 292 763, we know of fusion proteins, the ballast constituent of which consists of a β -galactosidase fragment with more than 250 amino acids. These fusion proteins are insoluble, but they can easily be rendered soluble with urea (EP-A 0 290 005).

Although fusion proteins have been described in the art, the generation of fusion proteins with desirable traits such as protease resistance is a laborious procedure and often results in fusion proteins that have a number of undesirable characteristics. Thus, a need exists for an efficient process for producing fusion proteins with a number of attractive traits including protease resistance, proper folding, and effective cleavage of the ballast from the desired protein.

SUMMARY OF THE INVENTION

The present invention relates to a process for the preparation of fusion proteins. Fusion proteins of the present invention contain a desired protein and a ballast constituent. The process of the present invention involves generating an oligonucleotide

-3-

library (mixture) coding for ballast constituents, inserting the mixed oligonucleotide (library) into a vector so that the oligonucleotide is functionally linked to a regulatory region and to the structural gene coding for the said desired protein, and transforming host cells with the so-obtained vector population. Transformants are then selected which express a fusion protein in high yield.

The process of the present invention further includes oligonucleotide coding for an amino acid or for a group of amino acids which allows an easy cleavage of the desired protein from the said ballast constituent. The cleavage may be enzymatic or chemical.

The invention also pertains to an oligonucleotide designed so that it leads to an insoluble fusion protein which can easily be solubilized. Fusion proteins of the present invention thus fulfill the requirements established for protease resistance.

Furthermore, oligonucleotide of the present invention may be designed so that the ballast constituent does not interfere with folding of the desired protein.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 and its continuation in Figure 1a and Figure 1b show the construction of plasmid population (gene bank) pINT4x from the known plasmid pH154/25* via plasmid pINT40. Other constructions have not been graphically presented because they are readily apparent from the figures.

Figure 2 is a map of plasmid pUH10 containing the complete HMG CoA reductase gene.

-4-

Figures 3 and 3a show construction of pIK4, a plasmid containing the mini-proinsulin gene.

DETAILED DESCRIPTION OF THE INVENTION

5 The invention relates to a process for the preparation of a fusion protein characterized in that a mixed oligonucleotide is constructed which codes for the ballast constituent of the fusion protein. The oligonucleotide mixture is introduced in a vector in
10 such a manner that it is functionally linked to a regulatory region and to the structural gene for the desired protein. Appropriate host cells are transformed with the plasmid population obtained in this manner, and the clones producing a high yield of coded fusion protein are selected. Advantageous
15 embodiments of this invention are explained below:

The oligonucleotide advantageously codes at the 3'-end an amino acid or a group of amino acids which permits or permit easy and preferably enzymatic
20 cleavage of the ballast constituent from the desired protein. According to another implementation form, an oligonucleotide is constructed that yields an insoluble fusion protein which can easily be made soluble. In particular, an oligonucleotide is preferably constructed which codes for a ballast
25 constituent that does not disturb the folding of the desired protein.

For practical reasons, the construction, according to the invention, of the oligonucleotide for the ballast constituent causes the latter to be very
30 short.

It was surprising to observe that, even when they have an extremely short ballast constituent, fusion proteins not only fulfill the requirements established

-5-

for protease resistance, but are also produced at a high expression rate and, if desired, the fusion protein is insoluble, can easily be rendered soluble. In the dissolved or soluble state, the short ballast constituent according to the invention then permits a sterically favorable conformation of the desired protein so that it can be properly folded and easily separated from the ballast constituent.

If the desired protein is formed in a pro-form, the ballast constituent can be constituted in such a manner that its cleavage can occur concomitantly with the transformation of the pro-protein into the mature protein. In insulin preparation, for example, the ballast constituent and the C chain can be removed simultaneously, yielding a derivative of the mature insulin which can be transformed into insulin without any side reactions involving much loss.

The short ballast constituent according to the invention is actually shorter than the usual signal sequences of proteins and does not disturb the folding of the desired protein. It therefore need not be eliminated prior to the final processing step yielding the mature protein.

The oligonucleotide coding for the ballast constituent preferably contains the DNA sequence (coding strand)

$$(DCD)_x$$

in which D stands for A, G or T and x is 4-12, preferably 4-8.

In particular, the oligonucleotide is characterized by the DNA sequence (coding strand)

$$ATG (DCD)_y (NNN)_z$$

in which N in the NNN triplet stands for identical or different nucleotides, excluding stop codons, z is 1-4

-6-

and y+z is 6-12, preferably 6-10, wherein y is at least 4. It has proved advantageous for the oligonucleotide to have the DNA sequence (coding strand)

5 ATG (DCD)₅₋₈ (NNN)
 especially if it has the DNA sequence (coding strand)
 ATG GCW (DCD)₄₋₈ CGW
 or, advantageously

 ATG GCA (DCD)₄₋₇ CGW
 10 in which W stands for A or T.

The above-mentioned DNA model sequences fulfill all of these requirements. Codon DCD codes for amino acids serine, threonine and alanine and therefore for a relatively hydrophilic protein chain. Stop codons
 15 are excluded and selection of the amino acids remains within manageable scope. The following is a particularly preferable embodiment of the DNA sequence for the ballast constituent, especially if the desired protein is proinsulin:

20 ATG GCW (DCD)_{y'} ACG CGW
 or

 ATG GCD (DCD)_{y'} ACG CGT
 in which y' signifies 3 to 6, especially 4 to 6.

The second codon, GCD, codes for alanine and
 25 completes the recognition sequence for the restriction enzyme NcoI, provided that the anterior regulation sequence ends with CC. The next to last triplet codes for threonine and, together with the codon CGT for arginine, represents the recognition sequence for
 30 restriction enzyme MluI. Consequently, this oligonucleotide can be easily and unambiguously incorporated in gene constructions.

The (NNN)z group codes in the 3' position for an amino acid or a group of amino acids that permits

-7-

simple, and preferably enzymatic, separation of the ballast constituent from the subsequent protein desired. It is expedient to select the nucleotides in this group in such a manner that at the 3'-end they code the cleavage site of a restriction enzyme which permits linkage of the structural gene for the desired protein. It is also advantageous for the ATG start codon and if necessary the first DCD triplet to be incorporated into the recognition sequence of a restriction enzyme so that the gene for the ballast constituent according to the invention can easily be inserted in the usual vectors.

The upper limit of z is obtained on the one hand from the desired cleavage site for (enzymatic) cleavage of the fusion protein obtained, i.e. it encompasses codons, for example, for the amino acid sequence Ile-Glu-Gly-Arg, in case cleavage is to be carried out with factor Xa. In general, the upper limit for the sum of y and z is 12, since the ballast constituent should of course be as small as possible and, above all, not interfere with the folding of the desired protein.

For reasons of expediency, bacteria or low eukaryotic cells such as yeasts are preferred as the host organism in genetic engineering processes, provided that higher organisms are not required. In these processes, the expression of the heterologous gene is regulated by a homologous regulatory region, i.e. one that is intrinsic to the host or compatible with the host cell. If a pre-peptide is expressed, it often occurs that the pre-sequence is also heterologous to the host cell. In practice, this lacking "sequence harmony" frequently results in variable and unpredictable protein yields. Since the

-8-

ballast sequence according to the invention is adapted to its environment, the selection process according to the invention yields a DNA construction characterized by this "sequence harmony".

5 The beginning and end of the ballast constituent are set in this construction: Methionine is at the beginning, and an amino acid or a group of amino acids that permit the desired separation of the ballast constituent from the desired protein is at the end.

10 If, for example, the desired protein is proinsulin, as NNN a triplet coding for arginine is advantageously selected as the last codon as this permits the particularly favorable simultaneous cleaving off of the ballast constituent with the removal of the C
15 chain. Of course, the end of the ballast constituent can also be an amino acid or a group of amino acids which allows a chemical cleavage, e.g. methionine, so that cleavage is possible with cyanogen bromide or chloride.

20 The intermediate amino acid sequence should be as short as possible so that folding of the desired protein is not affected. Moreover, this chain should be relatively hydrophilic so that solubilization is facilitated with undissolved fusion proteins and the
25 fusion protein remains soluble. Cysteine residues are undesirable since they can interfere with the formation of the disulfide bridges.

30 The DNA coding for the ballast constituent is synthesized in the form of a mixed oligonucleotide; it is incorporated in a suitable expression plasmid immediately in front of the structural gene for the desired protein and E. coli is transformed with the gene bank obtained in this manner. Appropriate gene structures can be obtained in this way by the

-9-

selection of bacterial clones that produce corresponding fusion proteins.

It was previously mentioned that the cleavage sites for the restriction enzymes at the beginning and end of the nucleotide sequence coding for the ballast constituent are to be regarded as examples only. Recognition sequences that encompass starting codon ATG and in which any nucleotides that follow may include the codon for suitable amino acids are, by way of example, also those for restriction enzymes AflIII, NdeI, NlaIII, NspHI or StyI. Since in the preferred embodiment arginine is to be at the end of the ballast sequence and since there are six different codons for arginine, additional appropriate restriction enzymes can also be found here for use instead of MluI, i.e., NruI, AvrII, AflIII, ClaI or HaeII.

However, it is also advantageous to use a "polymerase chain reaction" (PCR) according to Saiki, R.K. et al., Science 239:487-491, 1988, which can dispense with the construction of specific recognition sites for restriction enzymes.

It was previously indicated that limitation to the DNA sequence (DCD)_x is for reasons of expediency and that this does not rule out other codons such as, for example, those for glycine, proline, lysine, methionine or asparagine.

The most efficient embodiment of this DNA sequence is obtained by selection of good producers of the fusion protein, i.e., the fusion protein containing proinsulin. This yields the most favorable combination of regulation sequence, ballast sequence and desired protein, as a result of which unfavorable combinations of promoter, ballast sequence and structural gene are avoided and good results are

-10-

obtained with minimum expenditure in terms of the above-mentioned "sequence harmony".

Surprisingly, it was observed that the genes optimized for the ballast constituent according to the invention do not always contain the triplets preferred by E. coli. It was found that for Thr, codon ACA, which is used least frequently by E. coli, actually occurs frequently in the selected sequences. If, for example, the following amino acid sequence were optimized according to the preferred codon usage (p.c.u.) by E. coli (p.c.u.: Aota, S. et al., Nucleic Acids Research 16 (supplement): r315, r316, r391, r402 (1988)), we would obtain a totally different gene structure than that obtained according to the invention (Cf. Table 1):

Ala	Thr	Thr	Ser	Thr	Ala	Thr	Thr	
GCG	ACC	ACC	AGC	ACC	GCG	ACC	ACC	p.c.u.
GCA	ACA	ACA	TCA	ACA	GCA	ACT	ACG	invention

In the case of the fusion proteins with a proinsulin constituent, the initial starting point was a ballast constituent with 10 amino acids. The DNA sequence of the best producer then served as the base for variations in this sequence, whereupon it was noted that up to 3 amino acids can be eliminated without a noticeable loss in the relative expression rate. This finding is not only surprising, since it was unexpected that such a short ballast protein would be adequate, but also very advantageous since of course the relative proportion of proinsulin in the fusion protein increases as the ballast constituent decreases.

The significance of the ballast constituent in the protein is apparent from the following comparison:

-11-

Human proinsulin contains 86 amino acids. If, for a fusion protein according to EP-A 0 290 005, we take the lower limit of 250 amino acids for the ballast constituent, the fusion protein has 336 amino acids, only about one quarter of which occur in the desired protein. By comparison, a fusion protein according to the invention with only 7 amino acids in the ballast constituent has 93 amino acids, the proinsulin constituent amounts to 92.5%. If the desired protein has many more amino acids than the proinsulin, the relationship between ballast and desired protein becomes even more favorable.

It has been mentioned on a number of occasions that as a desired protein proinsulin represents only one preferred embodiment of the invention. However, the invention also works with much larger fusion proteins for which a fusion protein with the active domain of human 3-hydroxy-3-methylglutaryl-coenzyme A-reductase (HMG) is mentioned as an example. This protein contains 461 amino acids. A gene coding for the latter is known e.g. from EP-A 292 803.

Having now generally described the invention, the same will be more readily understood through reference to the following examples which are provided by way of illustration, and are not intended to be limiting of the present invention, unless specified.

Example 1

Construction of the gene bank and selection of a clone with high expression

If not otherwise indicated, all media are prepared according to Maniatis, T.; Fritsch, E. F. and Sambrook, J.: Molecular Cloning, Cold Spring Harbor Laboratory (1982). TP medium consists of M9CA medium

-12-

but with a glucose and casamino acid content of 0.4% each. If not otherwise indicated, all media contain 50 µg/ml ampicillin. Bacterial growth during fermentation is determined by measurement of the optical density of the cultures at 600 nm (OD). Percentage data refer to weight if no other data is reported.

The starting material is plasmid pH154/25* (figure 1), which is known from EP-A 0 211 299 herein incorporated by reference. This plasmid contains a fusion protein gene (D'-Proin) linked to a trp-promoter and a resistance gene for resistance against the antibiotic ampicillin (Amp). The fusion protein gene codes a fusion protein that contains a fragment of the trpD-protein from E. coli (D') and monkey proinsulin (Proin). The gene structure of the plasmid results in a polycistronic mRNA, which codes for both the fusion protein and the resistance gene product. To suppress the formation of excess resistance gene product, initially the (commercial) trp-transcription terminator sequence (trpTer) (2) is introduced between the two structural genes. To do so, the plasmid is opened with EcoRI and the protruding ends are filled in with Klenow polymerase. The resulting DNA fragment with blunt ends is linked with the terminator sequence (2)

5'AGCCCGCCTAATGAGCGGGCTTTTTTTT3'

3'TCGGGCGGATTACTCGCCCGAAAAAAA5' (2)

which results in plasmid pINT12 (figure 1-(3)).

The starting plasmid pH154/25* contains a cleavage site for enzyme PvuI in the Amp gene, as well as a HindIII-cleavage site in the carboxyterminal area

-13-

of the trpD-fragment. Both cleavage sites are therefore also contained in pINT12. By cutting the plasmid (Figure 1-(3)) with PvuI and HindIII, it is split into two fragments from which the one containing the proinsulin gene (figure 1-(4)) is isolated. Plasmid pGATTP (figure 1a-(5)), which is structured in an analogous manner to (3) but which instead of the D'-Proin gene carries a gamma-interferon gene (Ifn) containing restriction cleavage sites NcoI and HindIII, is also cut with PvuI and HindIII and the fragment (figure 1a-(6)) with the promoter region is isolated. By ligation of this fragment (6) with the fragment (4) obtained from (3), we acquire plasmid pINT40 (figure 1a-(7)). The small fragment with the remainder of the gamma-interferon gene is cut from the latter with NcoI and MluI. The large fragment (figure 1b-(8)) is ligated with mixed oligonucleotide (9)

5'CATGGCDDCDDCDDCDDCDDCDDCDDCA3'

3'CGHHGHHGHHGHHGHHGHHGHHGHTGCGC5' (9)

in which D stands for A, G or T and H signifies the complementary nucleotide. This results in plasmid population (gene bank) pINT4x (figure 1b-(10)). Mixed oligonucleotides of the present invention may be obtained by techniques well known to those of skill in the art.

The mixed oligonucleotide (9) is obtained from the synthetic mixed oligonucleotide (9a)

TTCGGGTACCGHHGHHGHHGHHGHHGHHGHTGCGCAG5'

TTGCCCATGGC3' (9a)

-14-

which is filled in with Klenow polymerase and cut with MluI and Nco.

The strain E. coli WS3110 is transformed with the plasmid population (10) and the bacteria are plated on LB agar dishes. Six of the resulting bacterial clones are tested for their ability to produce a fusion protein with an insulin constituent. For this purpose, overnight cultures of the clones are prepared in LB medium, and 100 μ l aliquots of the cultures are mixed with 10.5 ml TP medium and shaken at 37°C. At OD600 = 1 the cultures are adjusted to 20 μ g/ml 3- β -indolylacrylic acid (IAA), a solution of 40 mg glucose in 100 ml water is added and the preparation is shaken for another three hours at 37°C. Subsequently 6 OD equivalents of the culture are removed, the bacteria contained therein are harvested by centrifugation and resuspended in 300 μ l test buffer (37.5 mM tris of pH 8.5, 7 M urea, 1% (w/v) SDS and 4% (v/v) 2-mercaptoethanol). The suspension is heated for five minutes, treated for two seconds with ultrasound to reduce viscosity and aliquots thereof are subsequently subjected to SDS-gel electrophoresis. With bacteria that produce fusion protein, we can expect a protein band with a molecular weight of 10,350 D. It is evident that one of the clones, pINT41 (Table 1), produces an appropriate protein in relatively large quantities while no such protein formation is seen with the remaining clones. An immune blot experiment with insulin-specific antibodies confirms that the protein coded by pINT41 contains an insulin constituent.

Table 1 shows the DNA and amino acid sequence of the ballast constituent for a number of plasmid constructs. In particular, table 1 illustrates the

-15-

DNA and amino acid sequence of the ballast constituent
in the pINT41 fusion protein.

Example 2

Selection of additional clones

To detect additional suitable clones, a method according to Helfman, D.M. et al. (Proc. Natl. Acad. Sci. USA 80:31-35, 1983) is used. TP-agar dishes, the medium of which contains an additional 40 μM /ml IAA, are utilized for this purpose. Fifteen minutes before use, the agar surface of the plates is coated with a 2-mm thick TP top agar layer, a nitrocellulose filter is placed on the latter and freshly transformed cells are placed on the filter. Copies are made of the filters which have grown bacteria colonies following incubation at 37°C, and the bacteria from the original filter are lysed. To accomplish this, the filters are exposed to a chloroform atmosphere in an desiccator for 15 minutes, subsequently moved slowly for six hours at room temperature in immune buffer (50 mM tris of pH 7.5, 150 mM NaCl, 5 mM MgCl_2 , and 3% (w/v) BSA), which contains an additional 1 μg /ml DNase I and 40 μg /ml lysozyme, and then washed twice for five minutes in washing buffer (50 mM tris of pH 7.5 and 150 mM NaCl). The filters are then incubated overnight at 3°C in immune buffer with insulin-specific antibodies, washed four times for five minutes with washing buffer, incubated for one hour in immune buffer with a protein A-horseradish peroxidase conjugate, washed again four times for five minutes with washing buffer and colonies that have bound antibodies are visualized with a color reaction. Clones pINT42 and pINT43, which also produce fairly large quantities of fusion protein, are found in this manner in 500 colonies. The DNA obtained by sequencing and the amino acid

-19-

sequences derived from it have also been reproduced in Table 1.

Example 3

Preparation of plasmid pINT41d.

5 Between the replication origin and the
trp-promoter, plasmid pINT41 contains a nonessential
DNA region which is flanked by cleavage sites for
enzyme Nsp(7524)1. To remove this region from the
10 plasmid, pINT41 is cut with NSP(7524)1, and the larger
of the resulting fragments is isolated and religated.
This gives rise to plasmid pINT41d, the DNA sequence
of which is reproduced in Table 2.

Example 4

Fermentation and processing of pINT41d-fusion protein

(i) Fermentation: A shaking culture in LB medium is prepared from E. coli W3110 transformed with pINT41d. Fifteen μ l of this culture, which has an OD = 2 are then put into 15.7 l TP medium and the suspension is fermented 16 hours at 37°C. The culture, which at this time has an OD = 13, is then adjusted to 20 μ g/ml IAA, and until the end of fermentation, after another five hours, a 50% (w/v) maltose solution is continuously pumped in at a rate of 100 ml/hour. An OD = 17.5 is attained in this process. At the end, the bacteria are harvested by centrifugation.

(ii) Rupture of Cells: The cells are resuspended in 400 ml/disintegration buffer (10 mM tris of pH 8.0, 5 mM EDTA) and disrupted in a French press. The fusion protein containing insulin is subsequently concentrated by 30 minutes of centrifugation at 23,500 g and washed with disintegration buffer. This yields 134 g sediment (moist substance).

(iii) Sulfitolysis: 12.5 g sediment (moist substance) from (ii) are stirred into 125 ml of an 8 M urea solution at 35°C. After stirring for thirty minutes, the solution is adjusted to pH 9.5 with sodium hydroxide solution and reacted with 1 g sodium sulfite. After an additional thirty minutes of stirring at 35°C, 0.25 g sodium tetrathionate is added and the mixture is again stirred for thirty minutes at 35°C.

-23-

(iv) DEAE-Anion exchange chromatography: The entire batch of (iii) is diluted with 250 ml buffer A (50 mM glycine, pH 9.0) and placed on a chromatography column which contains Fractogel^(R) TSK DEAE-650 (column volume 130 ml, column diameter 26 mm) equilibrated with buffer A. After washing with buffer A, the fusion protein-S-sulfonate is eluted with a salt gradient consisting of 250 ml each buffer A and buffer B (50 mM glycine of pH 9.0, 3 M urea and 1 M NaCl) at a flow rate of 3 ml/minute. The fractions containing fusion protein-S-sulfonate are then combined.

(v) Folding and enzymatic cleavage: The combined fractions from (iv) are diluted at 4°C in a volume ratio of 1 + 9 with folding buffer (50 mM glycine, pH 10.7) and per liter of the resulting dilution 410 mg ascorbic acid and 165 µl 2-mercaptoethanol are added at 4°C under gentle stirring. After correction of the pH value to pH 10.5, stirring is continued for another 4 hours at 4°C. Subsequently, solid N-(2-hydroxyethyl)-piperazine-N'-2-ethane sulfonic acid (HEPES) is added to an end concentration of 24 g per batch-liter. The mixture which now has pH 8 is digested with trypsin at 25°C. During the process, the enzyme concentration in the digestion mixture is 80 µg/l. The cleavage course is followed analytically by RP-HPLC. After two hours, digestion can be stopped by addition of 130 µg soy bean trypsin inhibitor. HPLC shows the formation of 19.8 mg di-Arg insulin from a mixture according to (iii). The identity of the cleavage product is confirmed by protein sequencing and comparative HPLC with reference substances. The di-Arg insulin can be chromatographically purified according to known

-24-

methods and transformed to insulin with carboxypeptidase B.

Example 5

Construction of plasmid pINT60

5 Plasmid pINT60 results in an insulin precursor, the ballast sequence of which consists of only nine amino acids. For construction of this plasmid, plasmid pINT40 is cut with Nco and MluI and the resulting vector fragment is isolated. The
10 oligonucleotide Insul5

TTCGGGTACCGTTGTTGTAGTTTGAGTTGCGCAG 5'
TTGCCCATGGC 3'

15 is then synthesized, filled in with Klenow polymerase and also cut with these two enzymes. The resulting DNA fragment is then ligated with the vector fragment to yield plasmid pINT60.

 Table 1 shows the DNA and amino acid sequence of the ballast constituent in this fusion protein.

20 Example 6

Construction of plasmid pINT67d

 Plasmid pINT67d is a derivative of pINT41d in which the codon of the amino acid in position nine of the ballast sequence is deleted. That is why, like
25 pINT60, it results in an insulin precursor with a ballast sequence of nine amino acids. A method according to Ho, S.N. et al. (Gene 77:51-59, 1989) is used for its construction. For this purpose, two separate PCR's are first performed with plasmid
30 pINT41d and the two oligonucleotide pairs

-25-

TIR: 5'-CTG AAA TGA GCT GTT GAC-3'
and
DTR8: 5'-CAC AAA TCG AGT TGC TGT TGA TGT TGT-3'
or
5 DTR9: 5'-ACA GCA ACT CGA TTT GTG AAC CAG CAC-3'
and
Insull: 5'-TCA TGT TTG ACA GCT TAT CAT-3'.

10 This produces two fragments that are partially
complementary to each other and when annealed with
each other code a similar insulin precursor as pINT41d
in which, however, the amino acid in position nine is
absent. For completion, the two fragments are
15 combined and subjected to another PCR together with
the oligonucleotides TIR and Insull. From the DNA
fragment obtained in this manner, the structural gene
of the insulin precursor is liberated with Nco and
Sall and purified. Plasmid pINT41d is then also cut
20 with these two enzymes, the vector fragment is
purified and subsequently ligated with the structural
gene fragment from the PCR to yield plasmid pINT67d.

The nucleotide and amino acid sequences for the
ballast region have been reproduced in Table 1.

25 Example 7

Construction of plasmid pINT68d

Like plasmid pINT67d, plasmid pINT68d is a
shortened derivative of plasmid pINT41d in which the
codons of the two amino acids in positions eight and
30 nine of the ballast sequence are deleted. It
therefore results in an insulin precursor with a
ballast sequence of only eight amino acids. The
procedure previously described in Example 6 is used

-26-

for its construction but with the two oligonucleotide pairs

TIR: 5'-CTG AAA TGA GCT GTT GAC-3'

and

5 DTR10: 5'-CAC AAA TCG TGC TGT TGA TGT TGT TGC-3'

or

DTR11: 5'-TCA ACA GCA CGA TTT GTG AAC CAG CAC-3'

and

Insu11: 5'-TCA TGT TTG ACA GCT TAT CAT-3'.

10 The nucleotide and amino acid sequences for the ballast region have been reproduced in Table 1.

Example 8

Construction of plasmid pINT69d

15 Plasmid pINT69d is also a shortened derivative of plasmid pINT41d in which, however, the codons of the three amino acids in positions seven, eight and nine of the ballast sequence have been deleted. It therefore results in an insulin precursor with a ballast sequence of only seven amino acids. The
20 procedure described in Example 6 is also used for its construction but with the two oligonucleotide pairs

TIR: 5'-CTG AAA TGA GCT GTT GAC-3'

and

DTR12: 5'-CAC AAA TCG TGT TGA TGT TGT TGC CAT-3'

25 or

DTR13: 5'-ACA TCA ACA CGA TTT GTG AAC CAG CAC-3'

and

Insu11: 5'-TCA TGT TTG ACA GCT TAT CAT-3'.

-27-

The nucleotide and amino acid sequences for the ballast region have been reproduced in Table 1.

Example 9

5 Construction of plasmid pINT72d

Plasmid pINT72d is a derivative of plasmid pINT69d in which the entire C-peptide gene region, with the exception of the first codon for the amino acid arginine, is deleted. Consequently, this results in a "miniproinsulin derivative" with an arginine residue instead of a C-chain. With plasmid pINT69d as a starting point, the procedure described in Example 6 is also used for its construction but with the two oligonucleotide pairs

15 TIR: 5'-CTG AAA TGA GCT GTT GAC-3'
and
Insu28: 5'-GAT GCC GCG GGT CTT GGG TGT-3'
or
Insu27: 5'-AAG ACC CGC GGC ATC GTG GAG-3'
20 and
Insu11: 5'-TCA TGT TTG ACA GCT TAT CAT-3'.

Example 10

Construction of plasmids pINT73d, pINT88d and pINT89d
25 Plasmid pINT73d is a derivative of plasmid pINT69d (Example 8), in which the insulin precursor gene is arranged two times in succession. The plasmid therefore results in the formation of a polycistronic mRNA, which can double the yield. For its
30 construction, a PCR reaction is carried out with plasmid pINT69d and the two oligonucleotides

Insu29: 5'-CTA GTA CTC GAG TTC AC-3'

-28-

and

Insu11: 5'-TCA TGT TTG ACA GCT TAT CAT-3'.

5 This gives rise to a fragment with the insulin precursor gene and the pertinent ribosome binding site which in its 5'-end region has a cleavage site for enzyme XhoI and in its 3'-end region a cleavage site for SalI. The fragment is cut with the two above-mentioned enzymes and purified. Plasmid pINT69d
10 is then linearized with SalI, the two DNA ends produced are dephosphorylated with phosphatase (from calf intestine) and ligated with the fragment from the PCR reaction to yield plasmid pINT73d.

15 In an analogous manner there are obtained plasmids pINT88d and pINT89d when plasmid pINT72d (Example 9) is modified analogously by arranging the "miniproinsulin gene" twice or thrice in sequence.

Example 11

Construction of plasmid pINL41d

20 The starting plasmid pRUD3 has a structure analogous to that of plasmid pGATTP. However, instead of the trp-promoter region, it contains a tac-promoter region which is flanked by cleavage sites for enzymes EcoRI and Nco. The plasmid is cut with EcoRI,
25 whereupon the protruding ends of the cleavage site are filled in with Klenow polymerase. Cutting is performed subsequently with Nco and the ensuing promoter fragment is isolated.

30 The trp-promoter of plasmid pINT41d is flanked by cleavage sites for enzymes PvuII and Nco. Since the plasmid has an additional cleavage site for PvuII, it is completely cut with Nco, but only partially with PvuII. The vector fragment, which is missing only the

-29-

promoter region, is then isolated from the ensuing fragments. This is then ligated with the tac-promoter fragment to yield plasmid pINL41d.

5 Example 12

Construction of plasmid pL41c

Plasmid pPL-lambda (which can be obtained from Pharmacia) has a lambda-pL-promoter region. The latter is flanked by nucleotide
10 sequences:

5'GATCTCTCACCTACCAAACAAT3'

and

5'AGCTAACTGACAGGAGAATCC3'.

Oligonucleotides

15 LPL3: 5' ATGAATTCGATCTCTCACCTACCAAACAAT 3'

and

LPL4: 5' TTGCCATGGGGATTCTCCTGTCAGTTAGCT 3'

are prepared for additional flanking of the promoter region with cleavage sites for enzymes EcoRI and Nco.
20 A PCR is carried out with these oligonucleotides and pPL-lambda and the resulting promoter fragment is cut with EcoRI and Nco and isolated. Plasmid pINL41d is then also cut with these two enzymes and the ensuing vector fragment, which has no promoter, is then
25 ligated with the lambda-pL-promoter fragment to yield plasmid pL41c.

-30-

Example 13

Construction of plasmid pL41d

5 The trp-transcription terminator located between the resistance gene and the fusion protein gene in plasmid pL41c is not effective in E. coli strains that are suitable for fermentation (e.g. E. coli N4830-1). For this reason, a polycistronic mRNA and with it a large quantity of resistance gene product are formed in fermentation. To prevent this side reaction, the

10 trp-terminator sequence is replaced by an effective terminator sequence of the E. coli-rrnB-operon. Plasmid pANGMA has a structure similar to that of plasmid pINT41d, but it has an angiogenin gene instead of the fusion protein gene and an rrnB-terminator

15 sequence (from commercial plasmid pKK223-3, which can be obtained from Pharmacia) instead of the trp-terminator sequence. The plasmid is cut with PvuI and SalI and the fragment containing the rrnB-terminator is isolated. Plasmid pL41c is then

20 also cut with these two enzymes and the fragment containing the insulin gene is isolated. The two isolated fragments are then ligated to yield plasmid pL41d.

Example 14

Construction of plasmid pINTLI

25 To prepare a plasmid for general use in the expression of fusion proteins, the proinsulin gene of plasmid pINT41d is replaced by a polylinker sequence. This gene is flanked by cleavage sites for enzymes

30 MluI and SalI. The plasmid is therefore cut with the help of the two above-mentioned enzymes and the vector fragment is isolated. This is then ligated, to yield

plasmid pINTLI, with the following two synthetic oligonucleotides

BstEII AccI EcoRI KpnI BamHI
 5' CGCGCCTGGTTACCTCGAGGTATACTACGAATTCGAGCTCGGTACCCGGGGATCC
 3' GGACCAATGGAGCTCCATATGATGCTTAAAGCTCGAGCCATGGGCCCTAGG
 XhoI SacI XmaI

SphI XbaI
 CTGCAGGCATGCAAGCTTGTCTAGAC -3'
 GACGTCCGTACGTTCTGAACAGATCTGAGCT-5'
 PstI HindIII (SalI).

Insertion of a gene coding for HMG CoA-reductase (active domain) in pINTLI and expression of the fusion protein

Table 3 represents the DNA and amino acid sequence of the gene HMG CoA-reductase. The synthetic gene for HMG CoA-reductase known from EP-A 0 292 803 (herein incorporated by reference) contains a cleavage site for BstEII in the region of amino acids Leu and Val in positions 3 and 4 (see Table 3). A protruding sequence corresponding to enzyme XbaI occurs at the end of the gene (in the noncoding area). The corresponding cleavage sites in the polylinker of plasmid pINTLI are in the same reading frame. Both cleavage sites are in each case singular.

Plasmid pUH10 contains the complete HMG gene (HMG fragments I, II, III, and IV), corresponding to the DNA sequence of table 3. Construction of pUH10 (figure 2) is described in EP-A 0 292 803 herein incorporated by reference. Briefly, special plasmids are prepared for the subcloning of the gene fragments HMG I to HMG IV and for the construction of the

-32-

complete gene. These plasmids are derived from the commercially available vectors pUC18, pUC19 and M13mp18 or M13mp19, with the polylinker region having been replaced by a new synthetic polylinker corresponding to DNA sequence VI

Nco EcoRI HindIII BamHI XbaI

5' VI-1a
AAT TGC CAT GGG CAT GCG GAA TTC CAA GCT TTG GAT CCA TCT AGA GGG
3' CG GTA CCC GTA CGC CTT AAG GTT CGA AAC CTA GGT AGA TCT CCC TCG A
VI-1b

These new plasmids have the advantage that, in contrast to the pUC and M13mp plasmids, they allow the cloning of DNA fragments having the protruding sequences for the restriction enzyme Nco. Moreover, the recognition sequences for the cleavage sites Nco, EcoRI, HindIII, BamHI, and XbaI are contained in the vectors in exactly the sequence in which they are present in the complete gene HMG, which facilitates the sequential cloning and the construction of this gene. Thus it is possible to subclone the gene fragments HMG I to HMG IV in the novel plasmids. After the gene fragments have been amplified, it is possible for the latter to be combined to give the complete gene (see below).

a. Preparation of vectors which contain DNA sequence VI

DNA sequence VI may be prepared by standard techniques. The commercially available plasmid pUC18 (or pUC19, M13mp18 or M13mp19) is opened with the restriction enzymes EcoRI/HindIII as stated by the manufacturer. The digestion mixture is fractionated by electrophoresis on a 1% agarose gel. The plasmid bands which have been visualized by ethidium bromide

-33-

staining are cut out and eluted from the agarose by electrophoresis. 20 fmol of the residual plasmid thus obtained are then ligated with 200 fmol of the DNA fragment corresponding to DNA sequence VI at room temperature overnight. A new cloning vector pSU18 (or pSU19, M13mUS18 or M13mUS19) is obtained. In contrast to the commercially available starting plasmids, the new plasmids can be cut with the restriction enzyme Nco. The restriction enzymes EcoRI and HindIII likewise cut the plasmids only once because the polylinker which is inserted via the EcoRI and HindIII cleavage sites destroys these cleavage sites which are originally present.

b. Preparation of the hybrid plasmids which contain the gene fragments HMG I to HMG IV.

i) Plasmid containing the gene fragment HMG I

The plasmid pSU18 is cut open with the restriction enzymes EcoRI and Nco in analogy to the description in Example 15 (a) above, and is ligated with the gene fragment I which has previously been phosphorylated.

ii) Plasmid containing the gene fragment HMG II

The plasmids with the gene subfragments HMG II-1, II-2 and II-3 are subjected to restriction enzyme digestion with EcoRI/MluI, MluI/BssHII or BssHII/HindIII to isolate the gene fragments HMG II-1, HMG II-2 or HMG II-3, respectively. The latter are

-34-

then ligated in a known manner into the plasmid pSU18 which has been opened with EcoRI/HindIII.

iii) Plasmid containing the gene fragment HMG III

5 The plasmids with the gene subfragments HMG III-1 and III-3 are digested with the restriction enzymes ~~EcoRI/HindIII~~ and then cut with ~~Sau96I~~ to isolate the gene fragment HMG III-1, or with BamHI/BanII to isolate the gene fragment HMG III-3. 10 These fragments can be inserted with the HMG III-2 fragment into a pSU18 plasmid which has been opened with HindIII/BamHI.

iv) Plasmid containing the gene fragment HMG IV

15 The plasmids with the gene subfragments HMG IV-(1+2) and IV-(3+4) are opened with the restriction enzymes EcoRI/BamHI and EcoRI/XbaI, respectively, and the gene fragments HMG IV-(1+2) and HMG IV-(3+4) are purified by electrophoresis. The resulting fragments 20 are then ligated into a pSU18 plasmid which has been opened with BamHI/XbaI and in which the EcoRI cleavage site has previously been destroyed with S1 nuclease as described below. A hybrid plasmid which still contains an additional AATT nucleotide sequence in the 25 DNA sequence IV is obtained. The hybrid plasmid is opened at this point by digestion with the restriction enzyme EcoRI, and the protruding AATT ends are removed with S1 nuclease. For this purpose, 1 µg of plasmid is, after EcoRI digestion, incubated with 2 units of 30 S1 nuclease in 50 mM sodium acetate buffer (pH 4.5),

-35-

containing 200 mM NaCl and 1 mM zinc chloride, at 20°C for 30 minutes. The plasmid is recircularized in a known manner via the blunt ends. A hybrid plasmid which contains the gene fragment IV is obtained.

5 c. Construction of the hybrid plasmid pUH10
which contains the DNA sequence V

10 The hybrid plasmid with the gene fragment HMG I is opened with EcoRI/HindIII and ligated with the fragment HMG II which is obtained by restriction enzyme digestion of the corresponding hybrid plasmid with EcoRI/HindIII. The resulting plasmid is then opened with HindIII/BamHI and ligated with the fragment HMG III which can be obtained from the corresponding plasmid using HindIII/BamHI. The
15 plasmid obtained in this way is in turn opened with BamHI/XbaI and linked to the fragment HMG IV which is obtained by digestion of the corresponding plasmid with BamHI/XbaI. The hybrid plasmid pUH10 which contains the complete HMG gene, corresponding to DNA
20 sequence V, is obtained. Figure 2 shows the map of pUH10 diagrammatically, with "ori" and "Ap^r" indicating the orientation in the residual plasmid corresponding to pUC18.

25 If pINTLI is cut with BstEII and XbaI and the large fragment is isolated, and if, on the other hand, plasmid pUH10 (figure 2) is digested with the same enzymes and the fragment which encompasses most of the DNA sequence V from this plasmid is isolated, after ligation of the two fragments we obtain a plasmid
30 which codes a fusion protein in which arginine follows the first eight amino acids in the ballast sequence of pINT41d (Table 1), which is followed, starting with

-36-

Leu³, by the structural gene of the active domain of HMG CoA-reductase. For purposes of comparison, the two initial plasmids are cut with enzymes Nco and XbaI and the corresponding fragments are ligated together, yielding a plasmid which codes, immediately after the start codon, the active domain of HMG CoA-reductase (in accordance with DNA sequence V of EP-A 0 292 803, see table 3).

~~Expression of the coded proteins occurs according~~
to Example 4. Following the breakup of the cells, centrifugation is performed whereupon the expected protein of approximately 55 kDa is determined in the supernatant by gel electrophoresis. The band for the fusion protein is much more intensive here than for the protein expressed directly. Individual portions of 100 µl of the supernatant are tested in undiluted form, in a dilution of 1:10 and in a dilution of 1:100 for the formation of mevalonate. As an additional comparison, the fusion protein according to Example 4 (fusion protein with proinsulin constituent) is tested; no activity is apparent in any of the three concentrations. The fusion protein with the HMG CoA-reductase constituent exhibits maximum activity in all three dilutions, while the product of the direct expression shows graduated activity governed by the concentration. This indicates better expression of the fusion protein by a factor of at least 100.

Example 16

Construction of plasmid pB70

Plasmid pINT41d is split with MluI and SalI and the large fragment is isolated. Plasmid pIK4 shown in figure 3a contains a gene for "mini-proinsulin," the C chain of which consists of arginine only.

The construction of this plasmid has previously been described in EP-A 0,347,781 (herein incorporated by reference). Briefly, the commercial plasmid pUC19 is opened using the restriction enzymes KpnI and PstI and the large fragment (figure 3-(1)) is separated through a 0.8% strength "Seaplaque" gel. This fragment is reacted with T4 DNA ligase using the DNA (figure 3-(2)) synthesized according to Table 4. Table 4 shows the sequence of gene fragment IK I, while table 5 represents the sequence of gene fragment IK II.

This ligation mixture then is incubated with competent E. coli 79/02 cells. The transformation mixture is plated out on IPTG/Xgal plates which contain 20 mg/l of ampicillin. The plasmid DNA is isolated from the white colonies and characterized by restriction and DNA sequence analysis. The desired plasmids are called pIK1 (figure 3).

Accordingly, the DNA (figure 3-(5)) according to Table 5 is ligated into pUC19 which has been opened using PstI and HindIII (figure 3-(4)). The plasmid pIK2 (figure 3) is obtained.

The DNA sequences (2) and (5) of figure 3 according to Table 4 and 5 are reisolated from the plasmids pIK1 and pIK2 and ligated with pUC19, which has been opened using KpnI and HindIII (figure 3-(7)).

-43-

The plasmid pIK3 (figure 3) is thus obtained which encodes for a modified human insulin sequence.

The plasmid pIK3 is opened using MluI and SpeI and the large fragment (figure 3a-(9)) is isolated. This is ligated with the DNA sequence (10)

	B30		A1	A2	A3	A4	A5	A6	A7	A8	A9	
	(Thr)	(Arg)	Gly	Ile	Val	Glu	Gln	Cys	Cys	(Thr)	(Ser)	(10)
5'	CG	CGT	GGT	ATC	GTT	GAA	CAA	TGT	TGT	A		3'
10	3'	A	CCA	TAG	CAA	CTT	GTT	ACA	ACA	TGA	TC	5'
	(MluI)											(SpeI)

which supplements the last codon of the B chain (B30) by one arginine codon and replaces the excised codon for the first 7 amino acids of the A chain and supplements the codon for the amino acids 8 and 9 of this chain. The plasmid pIK4 (figure 3a) is thus obtained which encodes for human mini-proinsulin.

In tables 4 and 5, the B- and A-chains of the insulin molecule are in each case indicated by the first and last amino acid. Next to the coding region in gene fragment IK II, there is a cleavage site for SalI which will be utilized in the following construction.

Plasmid pIK4 is cut with HpaI and SalI and the gene coding "mini-proinsulin" is isolated. This gene is ligated with the above-mentioned large fragment of pINT41d and the following synthetic DNA sequence.

			B ¹				
	(Thr)	Arg	Met	Gly	Arg	Phe	
30	CG	CGT	ATG	GGC	CGT	TTC	GTT
		A	TAC	CCG	GCA	AAG	CAA
	(MluI)						(HpaI)

This gives rise to plasmid pB70, which codes a fusion protein in which the ballast sequence (Table 1, line

-44-

1) is followed by amino acid sequence Met-Gly-Arg which is followed by the amino acid sequence of the "mini-proinsulin".

Example 17

By using the oligonucleotides listed below there are obtained plasmids pINT90d to pINT96d in analogy to the previous examples. An asterisk indicates the same encoded amino acid in the ballast constituent as in pINT41d.

pINT92 encodes a double mutation in the insulin derivative encoded by the plasmid pINT72d since the codon for Arg at the end of the ballast constituent and in the "mini C chain" is substituted by the codon for Met. Thus the expressed preproduct can be cleaved with cyanogen bromide.

We claim:

1. A process for the preparation of fusion proteins, which fusion proteins contain a desired protein and a ballast constituent, which process
5 comprises

(a) constructing a mixed oligonucleotide which codes for the said ballast constituent,

(b) inserting the said mixed oligonucleotide into a vector so that it is functionally linked to a
10 regulatory region and to the structural gene coding for the said desired protein,

(c) transforming host cells with the so-obtained vector population and

(d) selecting from the transformants one or
15 more clones expressing a fusion protein in high yield.

2. The process as claimed in claim 1, wherein the said oligonucleotide codes at its 3' end of the coding strand for an amino acid or for a group of amino acids which allows an easy cleavage of the said
20 desired protein from the said ballast constituent.

3. The process as claimed in claim 2, wherein said cleavage is an enzymatic cleavage.

4. The process as claimed in claim 1, wherein the said oligonucleotide is designed so that it leads
25 to a fusion protein which is soluble or which easily can be solubilized.

5. The process as claimed in claim 1, wherein the said oligonucleotide is designed so that the

-50-

ballast constituent does not interfere with folding of the said desired protein.

5 6. The process as claimed in claim 1, wherein the said oligonucleotide contains the DNA sequence (coding strand)

(DCD)_x

in which D is A, G or T and x is 4 to 12.

7. The process as claimed in claim 6, wherein x is 4 to 8.

10 8. The process as claimed in claim 5, wherein the said oligonucleotide has the sequence (coding strand)

ATG (DCD)_y (NNN)_z

15 wherein N stands for identical or different nucleotides, excluding stop codons for NNN, z is 1 to 4 and y + z is 6 to 12, y being at least 4.

9. The process as claimed in claim 8, wherein y + z is 6 to 10.

20 10. The process as claimed in claim 8, wherein y is 5 to 8 and z is 1.

11. The process as claimed in claim 6, wherein the said oligonucleotide has the sequence (coding strand)

ATG GCW (DCD)₄₋₈ CGW

25 in which W is A or T.

-51-

12. The process as claimed in claim 11, wherein the said oligonucleotide has the sequence

ATG GCA (DCD)₄₋₇ CGW.

5 13. The process as claimed in claim 1, wherein the said desired protein is a proinsulin and wherein the said oligonucleotide (coding strand) is

ATG GCW (DCD)_{y'} ACG CGW or

ATG GCD (DCD)_{y'} ACG CGT,

wherein D is A, G or T, W is A or T and y' is 3 to 6.

10 14. The process as claimed in claim 13, wherein y' is 4 to 6.

15. The process as claimed in claim 2, wherein the desired protein is a proinsulin.

15 16. The process as claimed in claim 15, wherein the proinsulin has a C chain which is different from that of human proinsulin.

20 17. The process as claimed in claim 16, wherein the gene for C chain is designed so that the C chain can be split off together with the said ballast constituent.

18. The process as claimed in claim 17, wherein the C chain consists of arginine.
